Fuel cells are presently commercially available and are being considered for commercial applications such as the production of electricity for military or commercial vehicles. Such fuel cells convert chemical energy of reactants into electrical energy for powering the vehicle. One of the problems with the presently available fuel cells is their inability to produce high current densities which has restricted their application to lower power vehicles. One of the reasons for the lack of high current density in fuel cells is their anode, which, in a hydrogen fuel cell, is operated at a hydrogen oxidation potential. Although the anode must be oxygen-reactive to perform the desired electrochemical reactions, the anode must not be so oxygen-reactive as to consume more than a fraction of the 82157476af
